Table of Contents

Important Notes – PLEASE READ CAREFULLY

- **Both the 6100 user manual and this manual should be thoroughly read and understood before installation and commissioning is undertaken.**
- **The 6100 and its associated connections must be installed, commissioned and maintained by a suitably trained, skilled and competent person.**
- **It is assumed that the person commissioning the system is aware of Protec Fire Detection equipment terminology and terms of reference.**
- **This equipment must be earthed and earth continuity must be preserved on broken segments of screened cable used anywhere in the system installation.**
- **This equipment is not guaranteed unless installed and commissioned in accordance with current national standards.**
- **This equipment WILL NOT operate as a fire alarm panel when the USB port is connected and is in commissioning mode.**
- **This equipment is not suitable as part of an I.T type power distribution system as defined in IEC 60364-3.**
- **It is perfectly normal for sealed lead acid batteries to vent small amounts of hydrogen when being charged. The 6100 is vented to dissipate any build up of hydrogen. The 6100 enclosure must not be not sealed in any way.**
- **A competent person trained to undertake such work MUST carry out any internal maintenance. There are no user serviceable parts inside the 6100. Opening the PCB housing will immediately invalidate the warranty.**

Performance of power supply: Pass
Durability of operational reliability, Temperature resistance: Pass
Durability of operational reliability, Vibration resistance: Pass
Durability of operational reliability, Electrical stability: Pass
Durability of operational reliability, Humidity resistance: Pass

CE This equipment has been manufactured in conformance with the requirements of all applicable EU council directives and regulations.

Electrical or electronic devices that are no longer serviceable must be collected separately and sent for environmentally compatible recycling (in accordance with the European Waste Electrical and Electronic Equipment Directive). To dispose of old electrical or electronic devices, you should use the return and collection systems put in place in the country concerned.

The policy of Protec Fire Detection plc is one of continuous improvement. As such we reserve the right to make changes to product specifications at any time and without prior notice. Errors and omissions excepted.

1.0 Items Supplied with the 6100

- User manual
- Installation and Commissioning Manual (this manual)
- Loop Commissioning Booklet (used to affix loop device barcode labels at the relevant addresses)
- 6100 Spares kit

2.0 Items and Information Required Prior to Commissioning

2.1 Site information required to commission the 6100

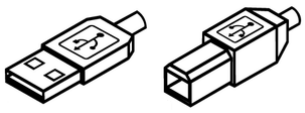
To ensure rapid and trouble-free commissioning the following information should be supplied to the commissioning engineer in advance of the proposed commissioning date.

- Loop device text (20 characters maximum per device)
- Zone text (20 characters maximum per zone)
- Panel text (2 lines of 20 characters maximum)
- Cause and effect programming, including ;

  Zone information
  Matrix information
  Delays to outputs
  Fire Link Delay
  Coincidence operation

2.2 Items required to commission the 6100 using the windows software

- Suitable PC with a USB port (please consult the 6100 programming manual for details of the recommended PC specification)
- 6100 commissioning software Windows program (and associated dongle if the system is managed)
- 6100 Programming Manual (available upon request, or from the Protec website)
- USB 2.0 Lead (Type A male to Type B male 2 metre maximum length), as illustrated below
  .



TYPE A **TYPE B**

3.0 Introduction and Key Features

The 6100 is a single loop fire alarm control panel incorporating an integrated power supply and high power loop driver circuit that communicates to a maximum of 192 Protec 6000Plus series detectors / sounders.and 6000 series interfaces.

The 6100 has been designed and manufactured in the United Kingdom and complies fully with current standards dictating fire alarm system design practice (EN54 parts 2 and 4).

Sophisticated tracking algorithms (Protec Algo-Tec™) are employed in the 6100 to discriminate between genuine and unwanted alarms, reducing the incidence of false alarms.

The integrity and reliability of a fire alarm system is paramount and consequently the 6100 continually monitors all critical paths for faults. The fire detection loop devices and wiring are constantly monitored to check for faults. The integrated power supply regularly performs self-checks to ensure it is fully working and that the stand-by batteries are in a good state.

Any alarms or faults detected are reported clearly on the front panel display and entered into a 300 event historic event log.

The key features include.

- High capacity single loop driver supporting a maximum of 192 Protec loop devices (detectors, sounders and interfaces)
- Clear controls and indications
- Intuitive menu system
- Uses Protec Algo-Tec™ detection algorithms to minimise unwanted alarms
- Two operating sensitivity levels may be set up per automatic detection device
- Sensitivity levels on detectors can be programmed to switch at preset times (Day / Night mode)
- Devices may be programmed into any one of 32 zones
- Monitored Fire Link output (including fire link delay, search time and disablement)
- Two monitored conventional alarm circuits (always driven as a pair)
- Global volt free fault and fire changeover contacts
- Monitored Auxiliary 24V output
- Programmable Remote Alarm input
- Programmable Class Change input
- Programmable Sound Alarms button operation
- Programmable conventional alarm output group
- Global walk test feature
- Alarm, zone, buzzer and Fire Link disablement
- Programmable T1 and T2 output group delays (output group specific)
- Programmable pulsing alarm timeout (global)
- Programmable coverage volume for EN54-23 compliant VAD devices
- Coincidence operation (to EN54 part 2 type C dependency)
- Global fire relay can operate on automatic, manual or all types of alarm
- Alarm counter (maximum of 9999 alarms)
- 300 event fire and non-fire historic logs
- Output groups may be programmed to be alarm or control type
- Loop devices may be individually programmed to be non-latching
- Programmable volume on loop sounders [note1]

Note 1: The loop sounder must have programmable volume capability

4.0 6100 Cabling Requirements

4.1 General

All wiring associated with the system must conform to the current I.E.E Regulations, and cabling must conform to the relevant BS specifications. ECA recommended cable separation for electromagnetic compatibility in buildings must be followed.

Where screened cables are used it is important to ensure that screen continuity is maintained between cable segments. Any screen wiring in the panel enclosure must be sleeved and securely bonded to the earth points provided.

For further information on cables, wiring and other interconnections please consult clause 26 of BS 5839 pt 1: 2013 (or any document superseding it).

4.2 Mains Input Rating Label

The mains rating label is located on the inner door of the 6100 and should be consulted before starting installation. The label details the working voltage, frequency and maximum current of the 6100.

4.3 Mains Wiring

The 6100 requires a mains supply exclusive to the panel that uses fixed three-core wiring (between 0.75mm^2 and 2.5mm^2) which is fed from a double pole isolating fused spur, fused at 3A.

Unauthorised operation of the mains supply must not be allowed and the fused spur should be labelled **" FIRE ALARM PANEL: DO NOT SWITCH OFF "**.

Mains wiring must be segregated from all other system wiring. The wiring clamp must be used to secure the incoming cables.

4.4 Alarm Circuit Wiring

Two alarm circuits are provided which are always driven simultaneously. Each alarm output can provide 100mA of current and must be terminated with the correct value end of line resistor, even if the alarm output is not used.

The gauge of the alarm circuit wiring must be chosen such that the volt drop along the wiring does not exceed specified limits. The maximum wiring resistance may be calculated using the following formula.

$$R_{wiring\_max} = (20.5 - V_{device\ min}) / (I_{device\ max})$$

Where R_{wiring_max} is the maximum resistance of the alarm circuit wiring (both conductors)
$V_{device\ min}$ is the minimum Voltage the alarm circuit devices are specified to work down to
$I_{device\ max}$ is the maximum total current that will be drawn on the alarm circuit

For example if alarm devices are specified to work to a minimum of 16V and the maximum alarm circuit current is 80mA, the maximum alarm cable resistance is 56.25Ω (28.13Ω per conductor).

To achieve an enhanced drive capability of 200mA it is permitted to connect both alarm circuits in parallel, in which case the end of line resistor must be reduced. Please see section 10.0 for end of line values.

Devices connected to the alarm circuits must be polarised and suppressed.

Alarm devices must not be connected on spurs from the main alarm circuit wiring as a spur will not be monitored for open circuit faults.

4.5 Fire Link Wiring

The fire link output may be used to signal an alarm condition to a remote monitoring station.

The fire link output is monitored for open and short circuit cable faults and, when used, must only connect to the Protec 6100 fire link end of line module. If the fire link output is not used it must be terminated locally in the panel (consult section 10.0 for details).

Suitably fire rated, screened cable must be used to connect the 6100 to the remote end of line module. The resistance of the cabling must be no more than 25Ω in total (12.5Ω per conductor).

4.6 Addressable Loop Wiring and Devices

The 6100 loop wiring carries both power and data to the loop devices. In order for the system to operate correctly under all conditions the voltage drop along the loop must be kept within specified limits.

The voltage drop on the loop is a function of both the resistance of the loop cabling (determined by the gauge of cable and the length of the loop) and the current that the loop must carry (determined by the number and type of loop devices connected).

The loop wiring must be wired from the panel terminals marked 'LA+ and LA-' round all the loop devices and reconnected at the panel terminal marked 'LB+ and LB-' (see figure 4.0).

Most Protec loop devices incorporate an integrated short circuit loop isolator. No more than 20 loop devices must be connected between isolators, and a loop isolating device **must always** be used on a zone boundary (a Manual Call Point is usually used for this purpose).

To comply with EN54-2 a Manual Call Point must be located next to the 6100, so that any system delays (if programmed) will be overridden by activation of the Manual Call Point at access level 1.

In the case of screened cables always ensure that individual segments have earth continuity (cable screen and / or drain wire is classed as earth), and that the earth wiring does not touch any other connections, or any other earthed points.

Figure 4.0 Typical 6100 loop configuration

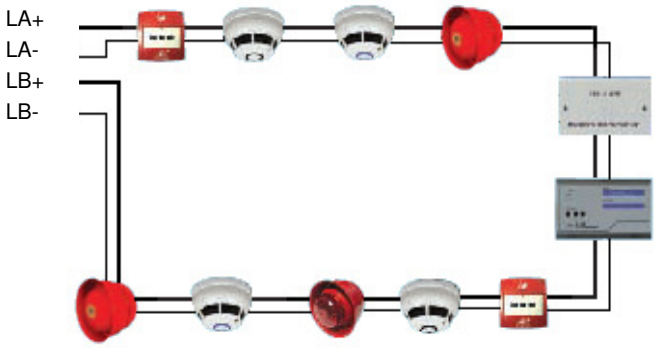


Table 4.0 shows the general characteristics required for the loop cabling.

Table 4.0 General loop cable requirements

Recommended Cable Type	Twin core twisted pair or twin core screened (screen must be connected to earth). **Four core cable must not be used.**
Recommended Cable Size	1.0mm^2 to 2.5mm^2
Maximum Cable Resistance	16Ω per conductor (dependent on loop volt drop calculations)
Maximum Cable Capacitance	0.22µF (220nF) per km between conductors
Maximum Cable Distance	1.5km (dependent on loop volt drop calculations)

Table 4.1 Guide to required cable size vs average loop current

		Loop Length (meters)										
		500	550	600	650	700	750	800	850	900	950	1000
Total loop load in alarm (mA)	50	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	100	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	150	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	200	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	250	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	300	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	350	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	400	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5
	450	1.0	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5	1.5	1.5
	500	1.0	1.0	1.0	1.0	1.5	1.5	1.5	1.5	1.5	1.5	2.5
	550	1.0	1.0	1.0	1.5	1.5	1.5	1.5	1.5	1.5	2.5	2.5
	600	1.0	1.0	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5

		Loop Length (meters)										
		1000	1050	1100	1150	1200	1250	1300	1350	1400	1450	1500
Total loop load in alarm (mA)	50	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	100	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	150	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	200	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	250	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	300	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	350	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	400	1.5	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5
	450	1.5	1.5	1.5	1.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5
	500	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	N/A
	550	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	N/A
	600	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5	N/A	N/A	N/A

5.0 Insulation Testing of Cabling Prior to Connection

Before connecting any external cables to any field device or the 6100, tests should be carried out using a 500V DC insulation tester (' Megger® '). If tests are performed the insulation readings between each cable core, and each cable core and earth must be greater than 10MΩ.

The 6100 or associated devices must not be connected to any cables when high voltage insulation tests are being performed on the cabling. The cabling must be completely discharged prior to connection to the 6100. Equipment connected to the cabling during insulation tests will be damaged by the high voltages used, invalidating any warranty.

6.0 Installing the 6100

The 6100 may be surface or flush mounted (no extra bezel is required when flush mounting).

The 6100 circuit board is fully enclosed within a sealed control PCB housing. The control PCB housing must never be opened. If the 6100 requires repair it must be sent back to the Protec factory.

The batteries are fully accessible with the control PCB housing removed from the back-box.

The 6100 must be located internally in an area that is not subject to dampness, direct sunlight, extremes of temperature or physical abuse. The environmental limits are given in section 8.0.

6.1 Unpacking

Carefully open the cardboard carton (do not use a sharp object) and remove the packing fitments, manuals and spares pack.

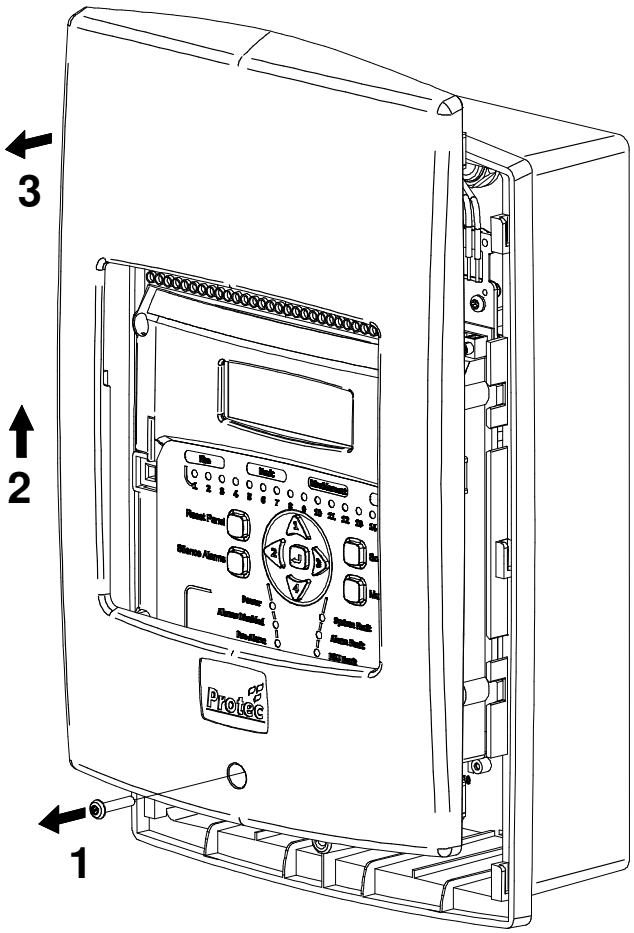
6.2 Removal of the Door

Remove the 6100 from the packaging then, using a T15 Torx® type security tool, unscrew but do not withdraw the fixing screw from the bottom of the panel housing front as shown in figure 6.0 stage 1. (stage 1).

Slide the door upward from the bottom and pull away as shown in figure 6.0 (stages 2 and 3).

Put all removed parts in a safe, dry place.

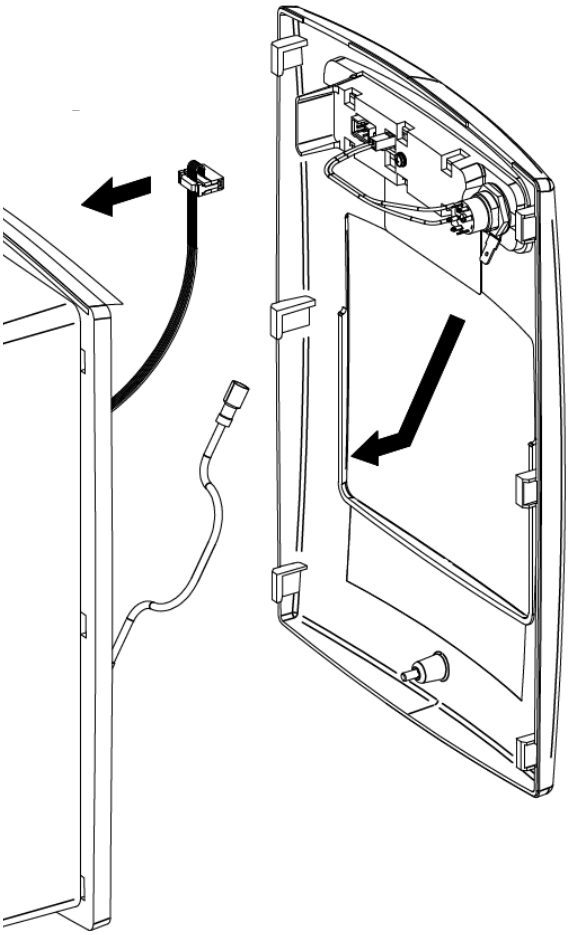
Figure 6.0 Removing the 6100 door



6.3 Disconnection of the Fire Brigade Panel (FBP) Connections

If the 6100 is equipped with the optional Fire Brigade Panel control interface ensure that the ribbon cable and earthing cable are disconnected from the rear of the controller as shown in figure 6.1.

Figure 6.1 Removing the FBP control interface connections



6.4 Removal of the Control PCB Housing

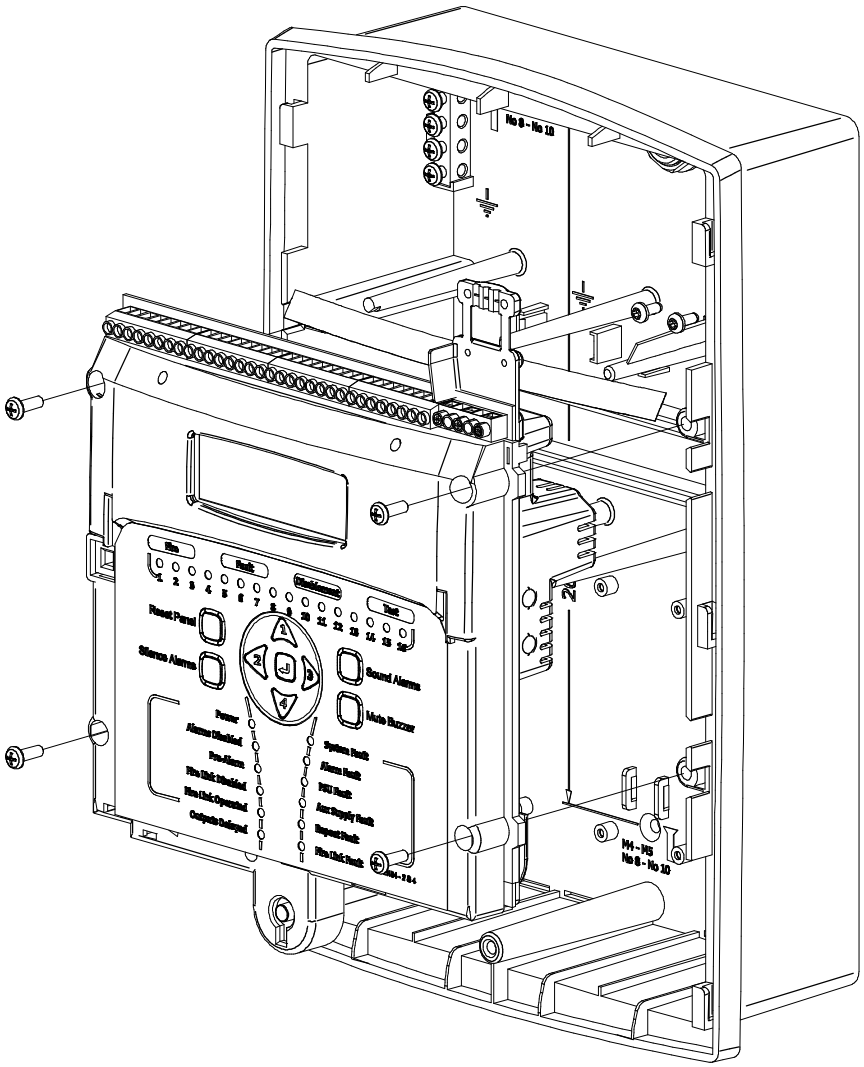
Before handling the 6100 panel control PCB housing it is important that any operatives discharge themselves of any static charge that may have built up. This can be done by momentarily touching a solid earth point (a non-painted part of a radiator, for example).

The Control PCB housing is a sealed unit and must not be opened. Tampering with this unit will invalidate the warranty. If the unit becomes faulty it must be returned for repair.

Unscrew and remove the four mounting screws on the control PCB housing. Carefully lift away the control PCB housing from the plastic enclosure. See figure 6.2.

The 6100 control PCB housing and all screws should be stored in the cardboard carton away from the place of work where they will not get damaged.

Figure 6.2 Removal of the 6100 Control PCB Housing



6.5 Preparing the Mounting Position and Cable Entries

Use the dimensions shown on the interior rear face of the 6100 back-box in conjunction with a spirit level to mark out the fixing locations for the panel. Drill and plug the mounting holes just marked.

Using a suitable tool carefully remove the rear panel knockouts at the required cable entry positions and mount the enclosure in position whilst feeding the cables into the enclosure via suitable glands.

The mains cable entry position *must* be segregated from all other system cabling, a reserved knock-out is provided specifically for this purpose.

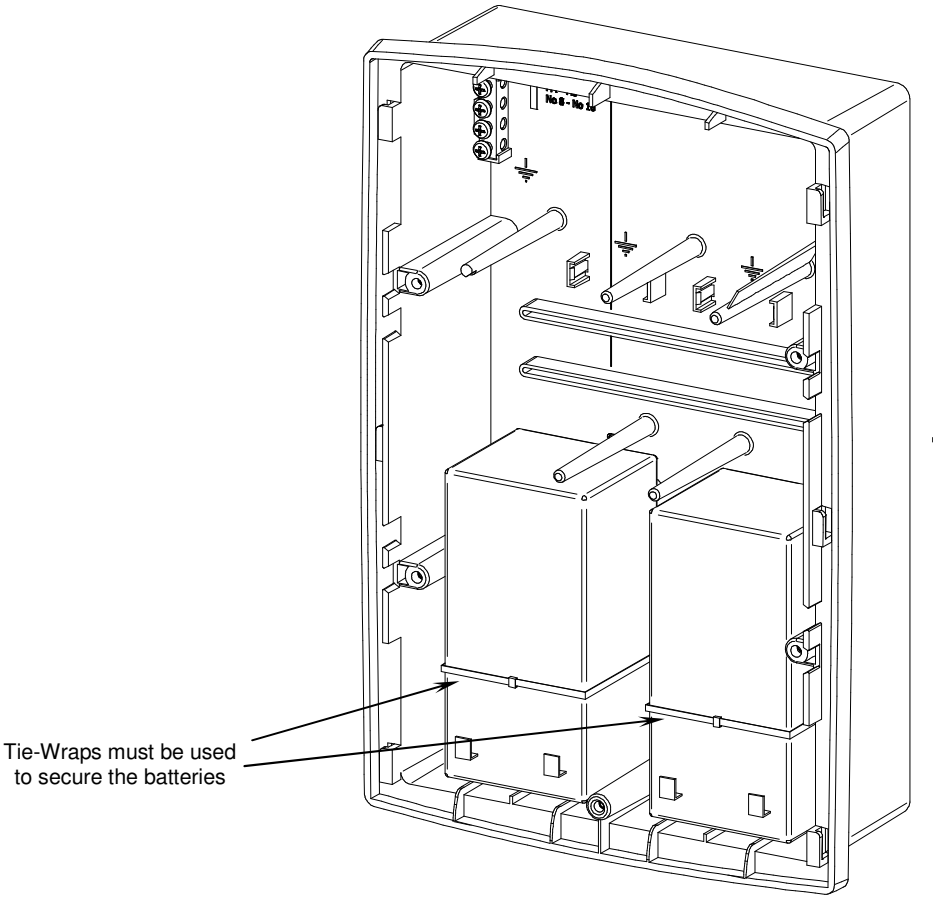
A four way brass earth block is supplied with the 6100. Three locations are provided for this in the 6100 back box. This allows the best location to be selected depending on wiring entry requirements. Choose the location then clip the earth block into the back box, ensuring it is securely fitted.

6.6 Installing the Standby Batteries

The 6100 is designed to house two 12V 3.3Ah Valve Regulated Lead Acid (VRLA) batteries. These fit into the back-box and must be secured with the two plastic tie-wraps provided (as shown in figure 6.3).

Only use batteries supplied or recommended by Protec. The internal charger has been specifically designed to maintain the charge voltage at an optimum level for these batteries over the entire operating temperature range in order to maximise the life of the batteries.

Figure 6.3 Installation of 6100 standby batteries (shown with the lid and control PCB housing removed)

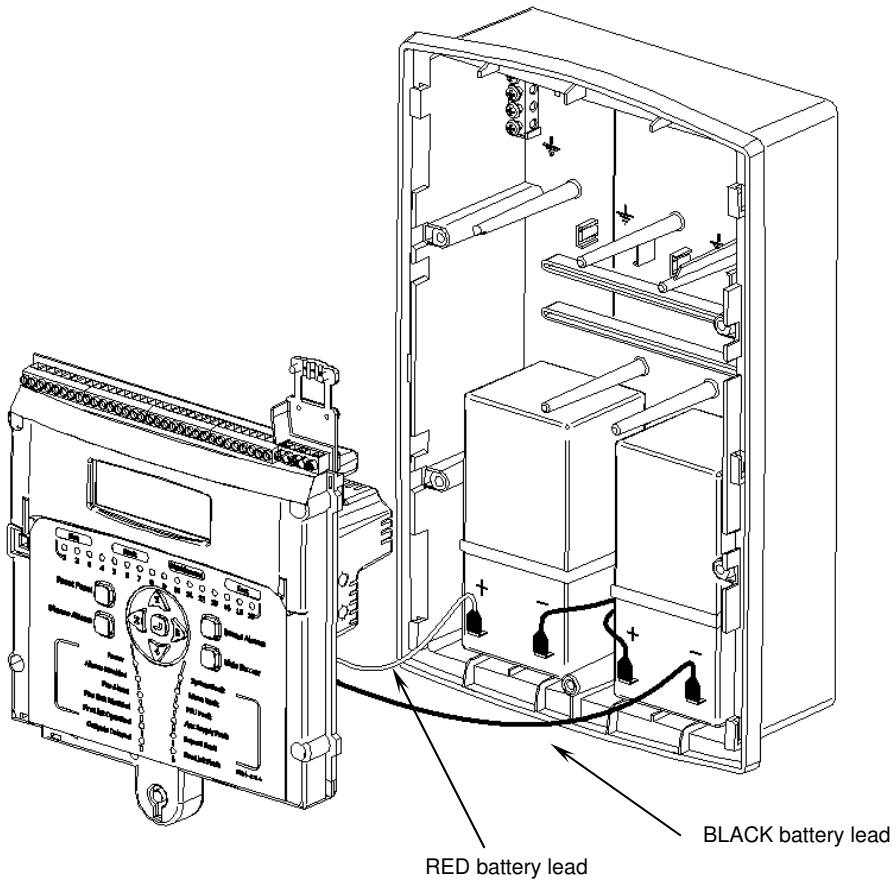


6.7 Connecting the Standby Batteries

The two standby batteries must be connected in series with the battery link provided. Then, observing correct polarity (red lead to the positive of one battery and black lead to the negative of the other battery), carefully push the spade connectors of the 6100 battery leads onto the relevant battery terminals (illustrated in figure 6.4).

Please note that at this point the 6100 will not power up until the mains supply is connected.

Figure 6.4 Standby battery connections



6.8 Refitting the Control PCB Housing

Ensure that all cable earth connections are sleeved to insulate them and then securely connect them to the brass earth terminals in the back-box.

Carefully route the battery leads (from the rear of the control PCB housing) down between the two batteries.

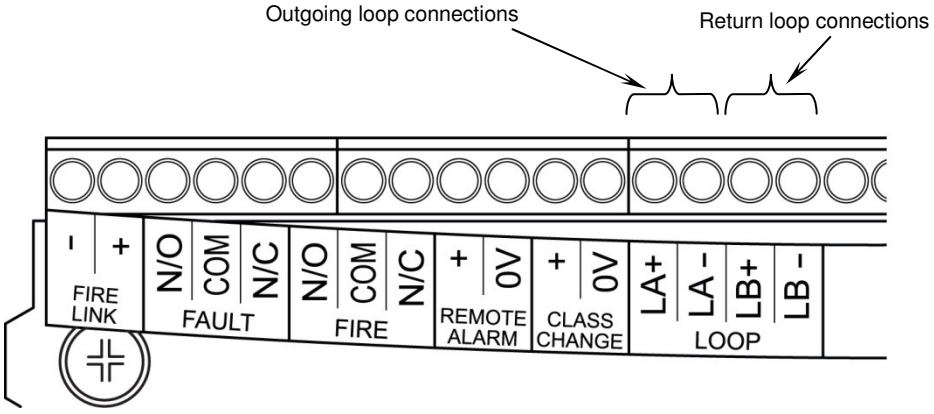
If the 6100 is equipped with a fire brigade panel controller, ensure the ribbon cable connected to the back of the control PCB housing is located over the top of the control PCB housing when refitting into the back-box.

Replace the control PCB housing (a reversal of removal), ensuring it is pushed flush to the back box and that the battery leads do not get trapped. Secure with the four screws removed previously, taking care not to over tighten the screws.

6.9 Connecting the Addressable Loop Wiring

The 6100 loop wiring must always be connected as a complete loop (LA + and LA - connections) to each device, then back to the panel again (LB + and LB - connections). Please see figure 6.5 and refer to figure 4.0.

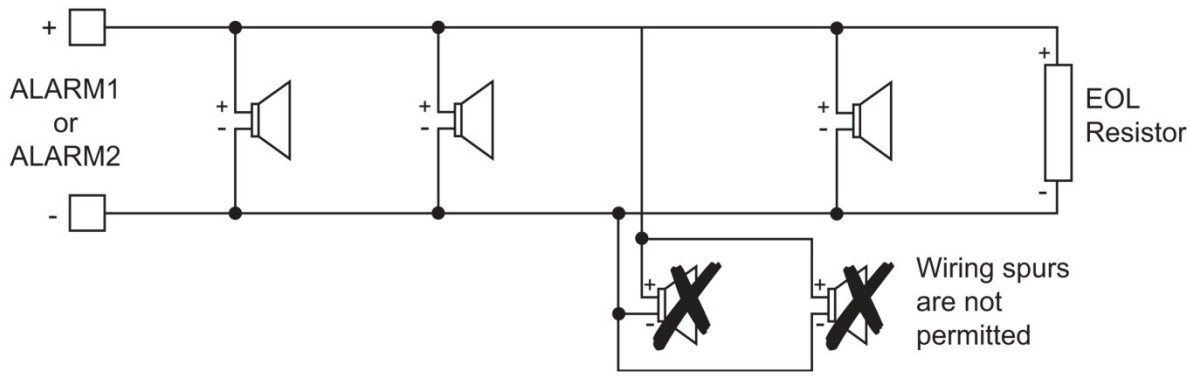
Figure 6.5 Loop Connection Details



6.10 Connecting the Conventional Alarm Circuit Wiring

The 6100 can drive two conventional alarm outputs. These must be connected as shown in figure 6.6. Unused outputs must still be terminated with an end of line resistor locally in the panel.

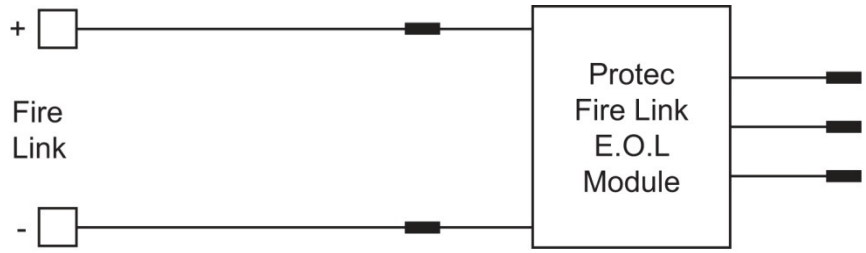
Figure 6.6 Conventional Alarm Output Connection Details



6.11 Connecting the Fire Link Wiring

The 6100 is equipped with an output to signal to a remote monitoring station. This output is monitored for cable faults and must only be connected to the Protec Fire Link End of Line Module (see appendix 1 for stock code). The End of Line Module must be fitted in the remote equipment, and not in the 6100. If the fire link end of line module is not required, the fire link output must still be terminated with an end of line resistor.

Figure 6.7 Fire Link Connection Details



6.12 Connecting the Auxiliary Wiring

The auxiliary wiring must now be connected if required. The auxiliary wiring comprises the class change input, remote alarm input, auxiliary 24V supply output, global fire contacts and global fault contacts. Note that these connections are optional and if not used do not require any termination.

Figure 6.8 Auxiliary 24V Output Details

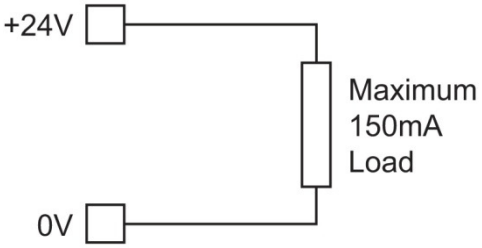


Figure 6.9 Remote Alarm Input Wiring

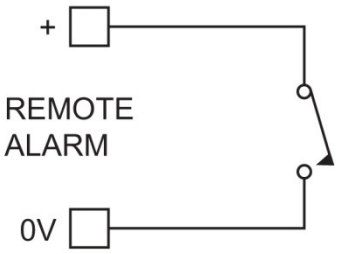

Figure 6.10 Class Change Input Wiring

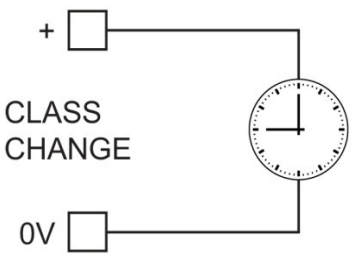

6.13 Connecting the Mains Cabling

Isolate the incoming mains supply by ensuring the fused double pole isolator is in the 'OFF' position.

Pay particular attention that the incoming mains cable is segregated from all other cables within the 6100 enclosure.

Ensure the incoming earth cable is firmly connected to the Main PCB (see figure 6.11), and that the earth cable from the Main PCB is securely connected to the brass earth terminals within the back-box.

The mains wiring must now be restrained using the clamp provided to secure the mains cables to the control PCB housing (see figure 6.12). The restraining clamp must be supported at the rear when the two screws are being tightened.

Figure 6.11 Power Supply Terminal Details

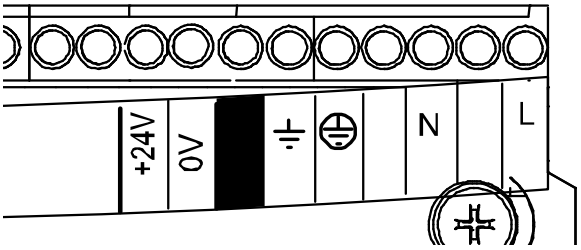

Figure 6.12 Mains wiring connections

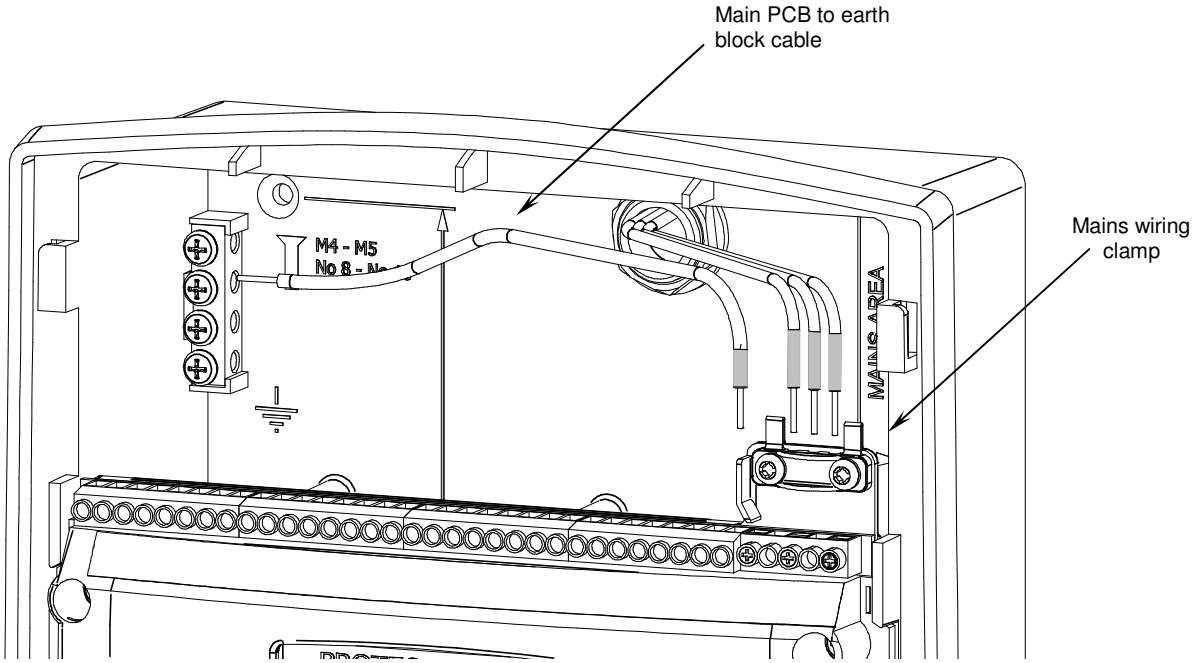
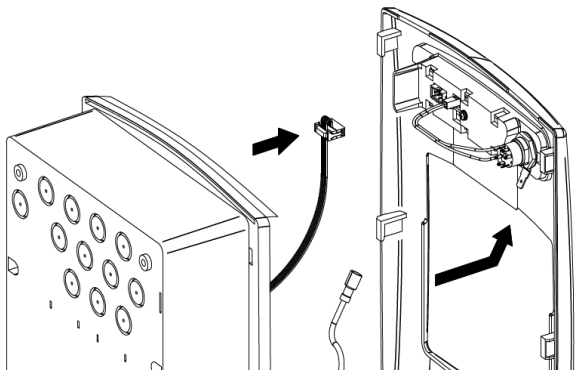


6.14 Connecting the Fire Brigade Panel Controller

If the 6100 is equipped with the optional Fire Brigade Panel control interface ensure that the ribbon cable and key-switch earthing cable are re-connected to the rear of the controller as shown in figure 6.13.

Figure 6.13 Reconnecting the Fire Brigade Panel Connections

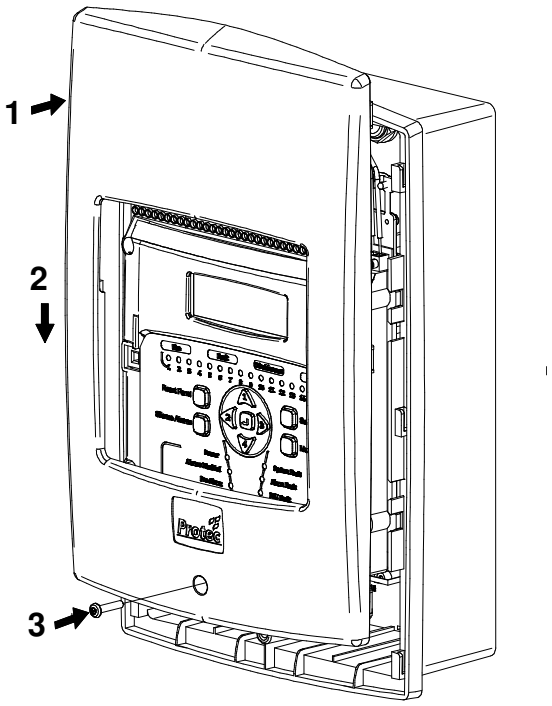


6.15 Re-fitting the Door

Before replacing the door ensure all mains, loop, alarm and auxiliary wiring has been completed and will not foul the door when it is refitted.

Replace the plastic door by raising the door and placing flush to the back-box of the panel (figure 6.14 step 1). Slide the door down and ensure it pushes fully home into the back box (figure 6.14 step 2). Finally screw in the fixing screw, taking care not to over tighten it (figure 6.14 step 3)

Figure 6.14 Refitting the 6100 door



6.16 Switching the Mains Power On

Switch the fused isolator to the 'ON' position. The green 'Power' indicator will illuminate and, assuming all other connections are correct, the 6100 should show one fault on the display (a 'panel reset ' fault). The 6100 is now ready to be programmed and commissioned.

7.0 Commissioning the 6100

The 6100 can be commissioned in a basic manner by using the menus, or more extensively using the Windows programming software. It is recommended that the Windows software is used (for a list of compatible PC hardware and operating systems please consult the 6100 programming manual).

It has been assumed that the time and date have been set (consult the user manual for details of how to do this).

7.1 Terminology

Loop input devices (Detectors, Manual Call Points, MIP's etc) are programmed into ***input groups*** and ***zones***.

Loop output devices (Sounders, CCO's etc) are programmed into ***output groups.***

How an activation from a device in a particular input group triggers output groups is determined by how the panel is programmed to execute it's cause and effects sequences (in the matrix).

Output groups are set to either Continuous (C), Warble (W), Pulsed (P) or Off (O), operation and activation is strictly by precedence (continuous, warble, pulsed and off. In that order).

7.2 Loop Device Input Group, Output Group and Zone Programming

Loop input devices must be programmed with an input group and zone appropriate to the cause and effects sequences required.

31 input groups are available for loop devices (please note that, if enabled, the 'Remote Alarm ' and ' Class Change ' inputs occupy inputs groups 31 and 30 respectively which cannot then be used by other input devices). Input group 32 is reserved for the Sound Alarms button.

Zone numbers range from 1 to 32 (inclusive).

Loop output devices must be programmed with an Output Group (1 to 32 inclusive) appropriate to the cause and effects sequence required.

7.3 Non latching Loop Devices

Loop devices may be individually programmed as non-latching. This means that when that device returns to normal after having been in alarm the 6100 will automatically reset (assuming no other devices have entered the alarm condition).

An activation from a non-latching device does not activate the global fire contacts.

Devices programmed to be non-latching usually need to be set as non latching on the device itself (please consult the relevant loop device datasheet for details).

7.4 Loop Device Class Programming

Loop devices may be programmed to belong to a certain class. The currently available class options are:

Automatic Class
Standard detection devices (for example, optical smoke detectors or heat detectors).

Manual Class
Manual Call Points are programmed as manual class. When activated, devices programmed as manual class will override any programmed system delays.

Silence, Reset, IReset, Sound Alarms and Accept Class
Loop devices programmed into any of these classes will mimic the relevant 6100 button press when activated. The loop device itself must be set to non-latching, **but not** programmed as non-latching on the 6100.

7.5 Loop Device Sensitivity Programming

This setting is only applicable to automatic detectors and allows two detection sensitivities to be programmed. The 6100 offers a range of sensitivities that can be used to tailor the response of the detector to suit individual site conditions. The 6100 supports the following sensitivities.

Table 7.0 Automatic Detector Sensitivity Setting Options

Programmed Sensitivity	Typical Applications
NONE	Used for non detector types (interfaces, MCP's etc)
OFFICE	For use in general environments (offices, for example)
BEDROOM	Incorporates an anti-steam algorithm for use in bedrooms
ENHANCED	Enhanced sensitivity for use in clean room environments
NO OP	Turns optical-heat devices into heat only devices *Note: The spacing distance for heat detectors must be adopted for the loop device if this sensitivity is used*
PRISON	Prison Cells

7.6 Loop Sounder Volume Programming

Individual loop sounder devices can have their volume level programmed. Volume settings of high, medium and low are supported (please consult the datasheet for the individual loop sounder product to ensure it can support programmable volume).

7.7 Talking Sounder Programming Considerations

The 6100 supports Protec talking sounders and special consideration must be given to them when programming. Talking sounders contain several pre-set messages that the control panel activates when required.

Talking sounders and non-talking output devices must not be mixed in the same output groups.

Talking sounders have a message synchronisation rate that is determined by programming at commissioning time. The typical synchronisation time is 20 seconds, which is sufficient to allow the longest standard audio message to be reproduced.

When the pulsing electronic bell sound is specified from a talking sounder (using setup features available in the Windows programming software) the standard system pulse rate is adopted.

Table 7.1 details how talking sounders operate with various panel activations.

Table 7.1 Talking Sounder Programming table

					Fire Activation			Walk Test Activation			Class Change		
Test Message	**Spoken Message**	**Bell Sound**	**Electronic Sounds**	**Male voice**	**C**	**P**	**W**	**C**	**P**	**W**	**C**	**P**	**W**
Off	√			Off	M1	M2	M3	Same as Fire Activation			M15	M14	M3
Off				√	M5	M6	M9						M5
Off		√		Off	M15	M14	M1						M3

M15 Continuous Bell

Key
√ Option selected
Off Option not selected

Notes
1. The Class Change messages do not function in a fire alarm condition.
2. The pulsing rate for message 14 is determined by the pulse times programmed.
3. Pressing Sound Alarms while in engineer or advanced engineer code produces message M4. If 'Sound Alarms' is pressed during a fire condition then test message M4 will replace the fire message.
4. Pressing Sound Alarms while in user exchange code produces message M7 however if a fire event occurs then 'Sound alarms' is cancelled and the appropriate fire message M1, M2 or M3 is output. If 'Sound Alarms' is pressed during a fire condition then, to avoid replacing the fire message with message M7, the output message will be determined by the cause and effect programming of the fire event and the sound alarms input group.

7.8 Fire Link Operation

Normal Operation
The fire link output activates within one second of the panel entering the alarm state (if a Fire Link delay has not been programmed).

The following 6100 activation's **will not** activate the Fire Link:

- Activation from a device programmed as Silence, Reset, IReset, Sound Alarms or Accept class
- Activation from a device in a zone that is programmed in walk test mode
- Activation from the Remote Alarm or Class Change inputs

Delayed Operation and Search Time
Using the Windows commissioning software the fire link activation can be programmed to be delayed by a fixed time. Upon a device activation the fire link delay timeout will begin, the fire link output then activates upon expiration of the delay. The maximum fire link delay time is 10 minutes.

A 'search time' of 0 to 10 minutes may also be programmed which is instigated by pressing the Mute Buzzer button at access levels 2 or 3 during the fire link delay. This gives an extra timeout before activation of the Fire Link occurs (search time can only be performed once until reset).

Note that the total Fire Link delay timeout is limited to 10 minutes, even if the Fire Link delay plus the search time exceeds 10 minutes.

An activation of a device programmed as manual class will override any Fire Link delay currently running.

Table 7.3 Effects of Panel Programming on Fire Link Operation

	Fire Link Disabled	Fire Link Delayed	Activation from a Non latching Device	Activation from a device in walk test zone	1st knock coincidence	2nd knock coincidence and Manual Class
Fire Link Disabled	Does not activate	Does not activate	Does not activate	Does not activate	Does not activate	Does not activate
Fire Link Delayed	Does not activate	Activates after delay time	Activates after delay timeout	Does not activate	See Note 1	See Note 2
Activation from a Non latching Device	Does not activate	Activates after delay time	Activates immediately	Does not activate	See Note 1	See Note 2
Activation from a device in walk test zone	Does not activate	Does not activate	Does not activate	Does not activate	Does not activate	Does not activate
1st knock coincidence	Does not activate	See Note 1	See Note 1	Does not activate	See Note 1	See Note 2
2nd knock coincidence and Manual class	Does not activate	See Note 2	See Note 2	Does not activate	See Note 2	See Note 2

Note 1:
The first activation to trigger the Fire Link takes precedence. For example, if an non-coincidence activation begins a Fire Link delay of 5 minutes, a first knock coincidence activation with a delay of 3 minutes will not override the original timeout.

Note 2:
The Fire Link will activate immediately if this feature has been enabled during commissioning. If the feature has not been enabled then the current Fire Link delay time will apply.

7.9 Global Fire Contact Operation

The 6100 controls a set of volt free changeover contacts that can be programmed to operate under various panel activation conditions. The fire contact connections are shown on the terminal label in the non fire state.

The contacts can be programmed to activate upon receipt of an activation from automatic class devices only, manual class devices only or both.

Devices set as anything other than automatic or manual class, programmed as non-latching, or in a walk test zone **will not** activate the contacts.

7.10 Global Fault Contact Operation

The 6100 will operate the global fault contacts under any fault condition (including when the panel is un-powered). The fault contacts connections are shown on the terminal label in the non fault state.

7.11 Remote Alarm Input Operation

The Remote Alarm input can be enabled and disabled by using the 6100 commissioning software. When enabled a remote alarm activation input triggers programming associated with input group 31. When the remote alarm input is enabled, input group 31 is not available for use by any other input device.

When the Remote Alarm input is disabled input group 31 becomes available for use as normal.

A remote alarm activation does not activate the Fire Link, or Global Fire contacts and can be configured to activate control output groups, or not.

The Remote Alarm input can also be configured (using the Windows commissioning software) to function as a Day / Night timer input. In this configuration the system switches the sensitivities of all automatic detectors to night mode when the remote alarm input is short circuited.

7.12 Class Change Input Operation

The Class Change input can be enabled and disabled by using the 6100 commissioning software. When enabled a class change input activation triggers programming associated with input group 30. When the class change input is enabled, input group 30 is not available for use by any other input device.

When the Class Change input is disabled input group 30 becomes available for use as normal.

Outputs will activate as programmed for input group 30 in the matrix, with the exception of talking devices which activate as shown below:

Activations from loop devices or the Remote Alarm input always override a Class Change activation.

Table 7.4 Class Change Input Operation of Talking Sounders

Matrix / panel programming	**Output from talking sounder when class change active**
Continuous	Continuous electronic bell sound will be reproduced
Pulse	Pulsing electronic bell sound will be reproduced
Warble and ‘Male Voice’ option disabled	The female evacuation message will be reproduced
Warble and ‘Male Voice’ option enabled	The male evacuation message will be reproduced
Off	Does not activate

7.13 Conventional Alarm Output Operation

The 6100 provides two conventional alarm outputs designed to drive 24V dc alarm devices. The alarm outputs are always driven as a pair and cannot be controlled separately.

The conventional alarm output can be programmed to follow any one of the 32 output groups, the operation is shown in table 7.5.

The conventional alarm outputs cannot be mapped to output groups containing talking devices.

Table 7.5 Conventional Alarm Output Operation

Output Group Activation	Conventional Alarm Activation
Continuous	Activates
Pulse	Pulses in accordance with system pulse times
Warble	Activates
Off	Does not activate

7.14 Output Group Type

Each output group can be individually set to be of type 'alarm', or 'control'. The operational differences between the two types are detailed in table 7.6.

Table 7.6

<table>
<tr><th>6100 Trigger Source</th><th>Alarm Output Group</th><th colspan="2">Control Output Group</th></tr>
<tr><td>Manual or Automatic class Loop device</td><td>Activates as programmed</td><td colspan="2">Activates as programmed</td></tr>

<tr><td rowspan="2">Remote Alarm</td><td rowspan="2">Activates as programmed</td><td>Setup to activate control groups</td><td>Setup not to activate control groups</td></tr>
<tr><td>Activates as programmed</td><td>Does not activate</td></tr>
<tr><td>Class Change</td><td>Activates as programmed</td><td colspan="2">Activates as programmed</td></tr>
<tr><td>6100 Silenced</td><td>Turns off current activation</td><td colspan="2">No change to current activation</td></tr>
<tr><td>6100 Reset</td><td>Turns off current activations and resets panel state</td><td colspan="2">Turns off current activations and resets panel state</td></tr>
</table>

7.15 Output Group Delays (T1 and T2)

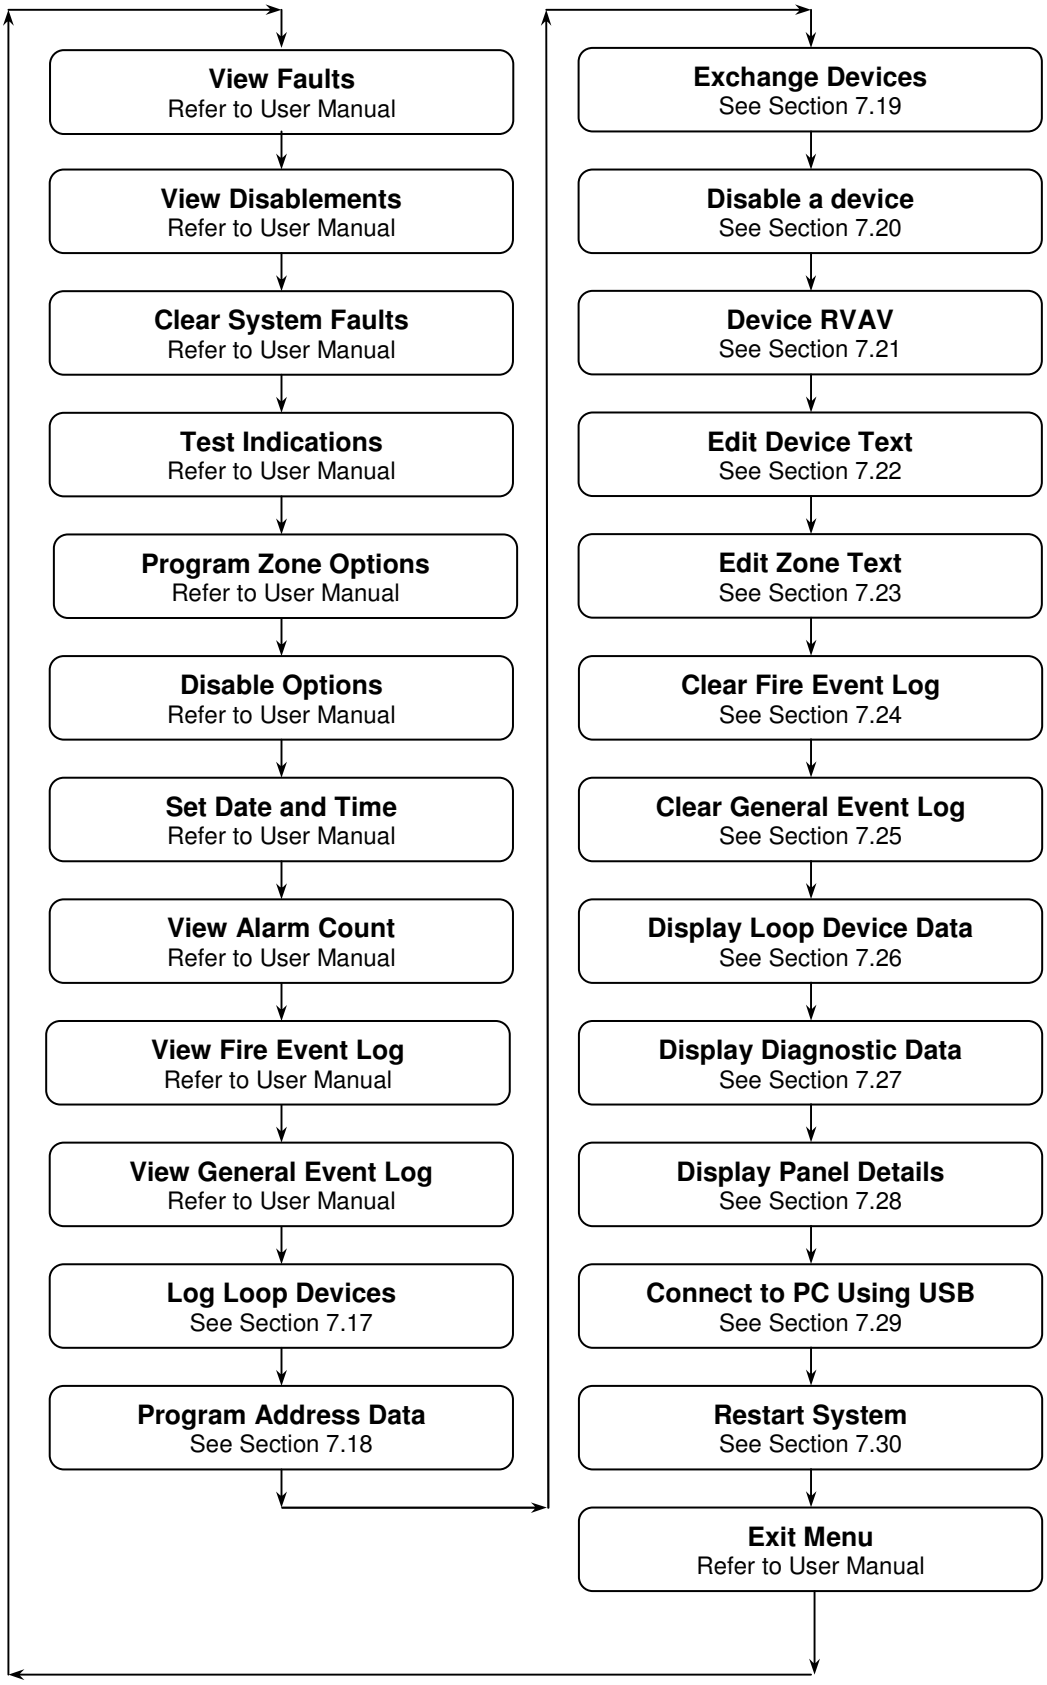
Each output group can have two delays introduced by appropriate programming in the Windows PC software. Delay 1 is termed 'T1' and delay 2 is termed 'T2'.

When an output group is activated by the cause and effects programmed into the 6100, the activation of the relevant output group can be delayed by up to 10 minutes for T1, and up to 20 minutes for T2. The T1 delay is introduced automatically, and T1 is replaced by T2 delay (if T2 is larger than T1) if the 'Mute Buzzer' button is pressed at access level 2 or 3 during an alarm condition.

The usual reason for using T1/T2 programming is to delay activation of sounders until the premises management reach the 6100 (T1 delay) and instigate a search time (T2 delay). The source of the alarm can then be investigated, and the panel reset if required.

T1/T2 delays will be cancelled by activation of a manual class device, or if the 6100 is in night mode and the 'Cancel Delays in Night Mode' option has been selected in the Windows software. Delays are not used when in 'Walk Test' mode.

Figure 7.0 – 6100 Engineer (Access level 3) Menu Structure



7.16 Programming the coverage volume of Visual Alarm Devices (VADs)

The coverage volume of EN54-23 compliant VADs may be set up on a device specific basis by appropriate programming in the Windows PC software.

This feature allows the individual coverage requirements of loop VADs to be tailored for the specific installation environment, which results in optimised system operating currents.

7.17 Logging and Mapping Loop Devices

Logging and mapping loop devices is the process the 6100 uses to work out how many, and what type of devices are connected to the loop, and where they are in relation to each other.

Before logging always ensure there are no loop faults on the panel

Logging and mapping could take up to 6 minutes, depending on the loop configuration

The 6100 WILL NOT detect fires during the logging and mapping phase

Logging
During the logging phase the 6100 drives the loop from sides A and B, all relevant devices connected to the loop are logged and stored in memory (devices will not be logged if the 6100 does not support the device type, or the software version of the device is not supported by the 6100).

When the 6100 has logged a loop device it searches the existing panel loop device data to see if the loop device is already logged and allocated on the system, if it is, the software version of the loop device is updated in memory. By doing this site files that have been created using a device serial number barcode scanner (which does not contain the device software version) and downloaded using the PC commissioning software are completed. The resulting 'complete' site file must always be uploaded from the panel to the PC and stored for backup.

Mapping
During the mapping phase the loop drives from side A only. Loop isolators on devices are sequentially closed and each group of devices between isolators are allocated an 'isolator node number'. As devices are sequentially mapped, data stored during the logging phase is checked, if the mapped device was not logged originally the mapping process will fail. Device loop isolators are closed sequentially until all logged devices have had their isolators closed, after which the panel has complete information of how the system is configured.

Please note, even if the mapping process fails, the logging data stored in memory may still be used to allocate loop devices onto the 6100, even though the isolator node data may not be present.

At the LOG LOOP DEVICES menu press the ↵ key to begin the loop logging sequence (as shown in figure 7.1 and 7.2)

Line 1 of the display indicates the logging and mapping progress, and has the following sections.

RESETTING LOOP
Displayed when the 6100 is resetting the loop to make sure all loop devices are ready to be logged.

LOGGING LOOP
Displayed when the 6100 is logging the loop devices.

LOGGING COMPLETE
Displayed when the 6100 has finished logging the loop devices and is preparing to map the loop devices. Logged device data is now in temporary memory.

MAPPING LOOP
Displayed when the 6100 is mapping the sections of the loop separated by loop isolators.

MAPPING SUCCESS
Displayed when the 6100 has successfully logged and mapped the loop. Mapping data is now in memory ready for loop devices to be allocated.

MAPPING FAILED
Displayed if the 6100 could not successfully log or map the loop. This could be because there are more than 192 devices on the loop.

Figure 7.1 6100 loop logging display

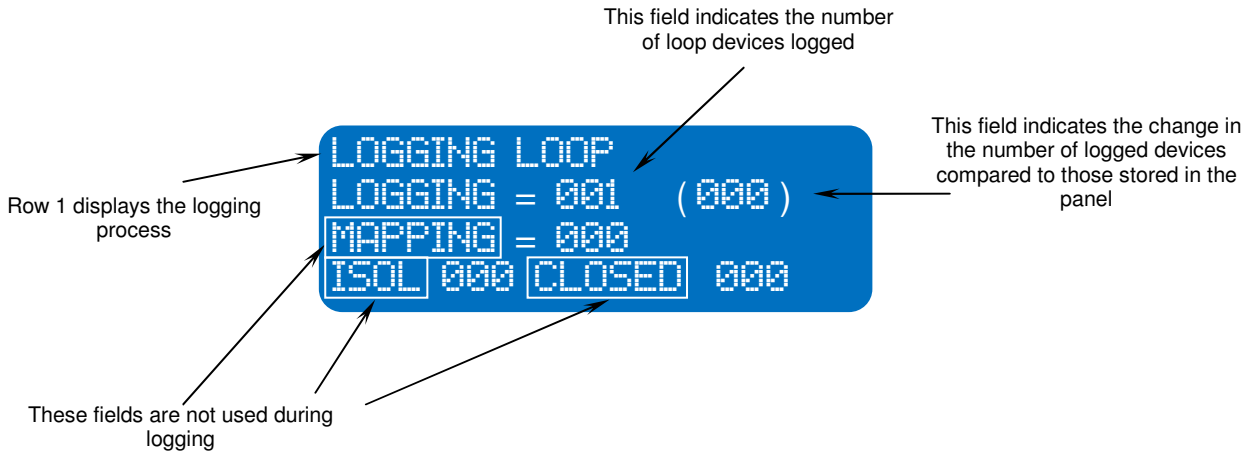


Figure 7.2 6100 loop mapping display

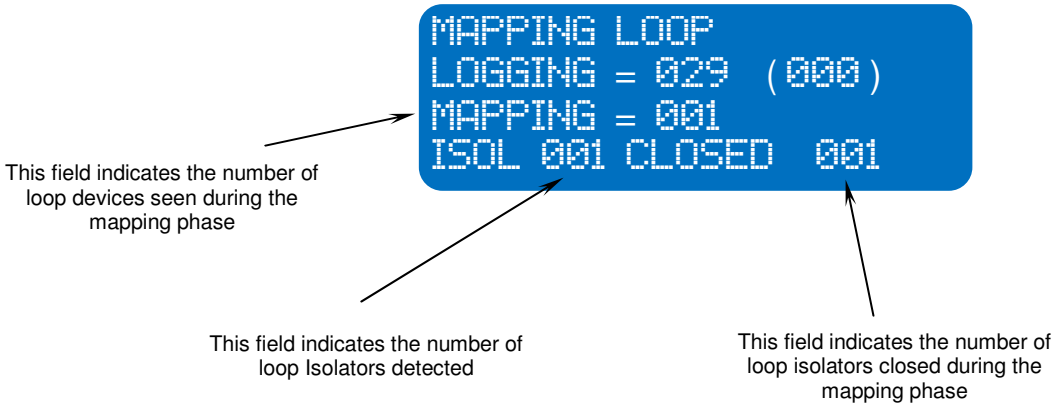


7.18 Programming Loop Device Address Data

If new loop devices are to be allocated the loop must be logged and mapped before entering this menu.

The loop devices temporarily stored during logging and mapping must be allocated certain operational parameters before the 6100 can process data from them. The PROGRAM ADDRESS DATA menu is used to achieve this.

At the PROGRAM ADDRESS DATA menu option press the ↵ key. A flashing cursor indicates which parameter is currently being edited. Note that choices are spread over multiple screens.

Also note that not all parameters apply to all device types (for example sensitivity setting is meaningless for a loop sounder, and volume is meaningless for a heat detector) non applicable device parameters can be still be set up but are not processed by the 6100.

With reference to figure 7.3

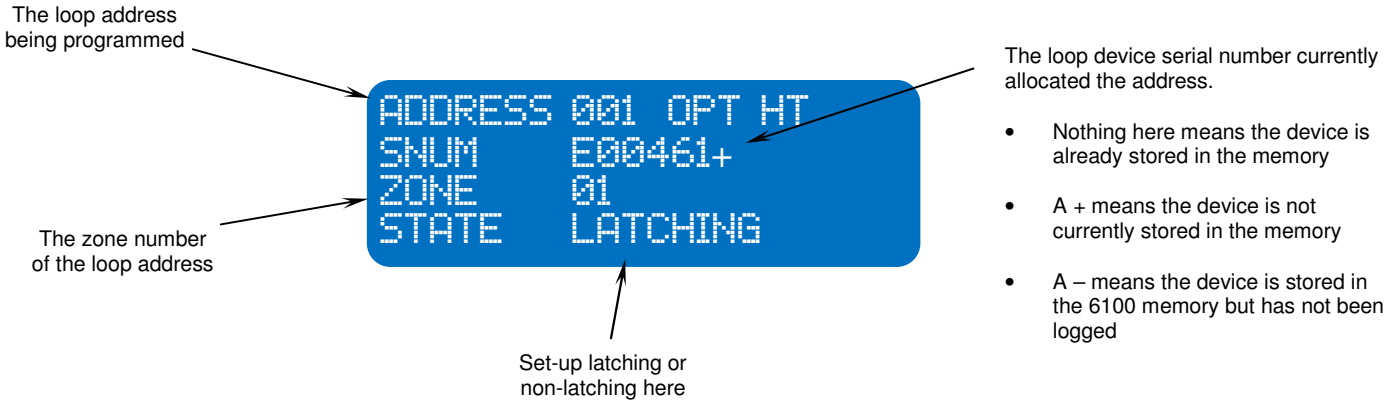
Selecting a loop address to edit its parameters
Using the ◄ or ► keys choose the loop ADDRESS to be edited.

To allocate a loop device serial number to the address
Use the ▲ and ▼ keys to select SNUM field.
Using the ◄ or ► keys link a currently unallocated loop devices to this address.
To de-allocate a device from this address select a SNUM of 000000, this then makes the loop device free to swap to another address or it can be left de-allocated (the 6100 will not process a de-allocated device).

To set the zone number for the address
Use the ▲ and ▼ keys to select ZONE field.
Use the ◄ or ► keys to set the zone number for the address, valid zone numbers are 1 to 32 inclusive.

To set address to be latching or non-latching
Use the ▲ and ▼ keys to select STATE field.
Use the ◄ or ► keys to toggle the state between LATCHING and NON LATCHING as required.

Figure 7.3 Program address screen 1



With reference to figure 7.4

To set the input group for the address
Use the ▲ and ▼ keys to select INPUT GROUP field.
Use the ◄ or ► keys to set the input group number for the address. Refer to section 7.2 for input group ranges.

To set the output group for the address
Use the ▲ and ▼ keys to select OUTPUT GROUP field.
Use the ◄ or ► keys to set the output group number for the address, valid output group numbers are 1 to 32 inclusive.

To set the volume level for the address
Use the ▲ and ▼ keys to select VOLUME field.
Use the ◄ or ► keys to set the required volume level for the loop sounder. Valid levels are LOW, MED and HIGH.

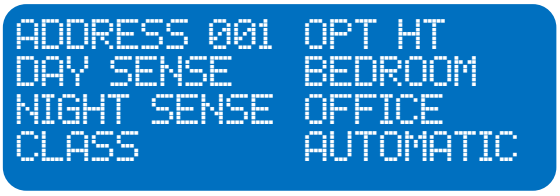
Figure 7.4 Program address screen 2

With reference to figure 7.5

To set the DAY and NIGHT sensitivities for the address
Use the ▲ and ▼ keys to select the DAY SENSE, or NIGHT SENSE field as required.
Use the ◄ or ► keys to set the required sensitivity level for the address. Refer to section 7.6 for input group ranges.

To set the CLASS data for the address
Use the ▲ and ▼ keys to select CLASS field.
Use the ◄ or ► keys to set the class for the address.

Figure 7.5 Program address screen 3



Press the ↵ key at any time to store any changes, the 6100 will warn that changes are to be made to the site data and the panel will reset and reboot as shown in figure 7.6.

Figure 7.6 Program address warning display

Press the ↵ key to accept, or the ◄, ►, ▲ or ▼ keys to decline and remain in the menu. Then, if possible, upload and save the site file on a PC.

7.19 Exchanging Loop Devices

Exchanging loop devices incorrectly can result in undefined system operation. If in doubt contact your service agent. Loop devices can only be exchanged with other loop devices of the same type. Any exchanged devices MUST be fully tested in all required modes to ensure they are fully operational.

1. Enter the user code supplied with the system and press the ↵ key to access the menus.
2. Scroll to the EXCHANGE DEVICES menu and press the ↵ key. The 6100 is now in exchange devices mode (figure 7.7). Up to 8 loop devices may be exchanged at a time.
3. Remove the device(s) that are to be exchanged and wait for the 6100 to declare them as missing.
4. Add the new device(s) in place of the old ones, ensuring the replacement device is of exactly the same type as the original. Wait for the 6100 to recognise them as added.
5. Press the ↵ key to access the final exchange menu (figure 7.8).
6. Take a note of the serial numbers, loop addresses and device text of the old and new devices.
7. Using the ◄, ▲, ► and ▼ keys locate old device(s) and swap with corresponding new device(s).
   The 6100 will only offer matching types to be exchanged. Update all devices to be exchanged as necessary.
8. Press the ↵ key to proceed to the exchange devices save confirmation as shown in figure 7.9.
9. Press the ↵ key to save the exchanged devices to the panel memory and reset the panel. Alternatively press the ◄, ▲, ► and▼ keys to exit this screen and return to the exchange devices display.

Figure 7.7 Exchange Devices Initialisation display

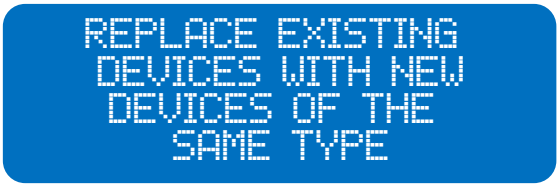


Figure 7.8 Exchange Devices display

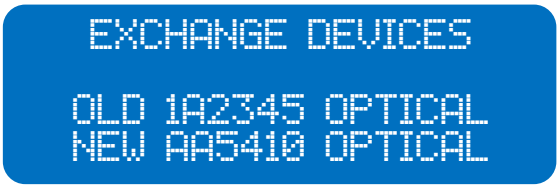

Figure 7.9 Exchange Devices Save confirmation display

7.20 Disabling / Enabling a Loop Device

1. Enter the engineer code supplied with the system and press the ↵ key to access the menus.
2. Scroll to the DISABLE A DEVICE menu and press the ↵ key.
3. Using the ◄ and ► keys select the device address to be disabled / enabled.

   The current disablement state of the address is displayed next to the address number, and any programmed address text is displayed on row 3 of the LCD.
4. Press the '▲' key to disable the address, or the '▼' key to enable the address.

Zone disablements take precedence over device disablements. A device that is in a disabled zone cannot be individually enabled. The whole zone must be enabled.

Figure 7.10 Device Disablement Screen

7.21 Loop Device Remote Visual Address Verification (RVAV)

The DEVICE RVAV menu allows loop devices to be programmed to indicate their address by flashing the indication LED to aid locating the device during commissioning.

Devices set to RVAV operation cannot detect a fire

At the DEVICE RVAV menu press the ↵ key the 6100 will warn that devices programmed to RVAV will not detect fires. The user may then accept this condition by pressing the ↵ key, or decline by pressing the ▲, ▼, ◄ or ► keys.

Figure 7.11 RVAV warning display

Figure 7.12 RVAV Range selection display

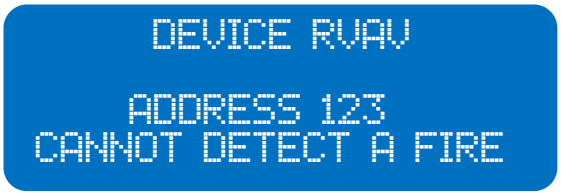
Using the ▲ or ▼ keys toggle the flashing cursor between the start and end address's to be set to RVAV.

Using the ◄ or ► keys set the address range as required.

Press the ↵ key to accept the range and set all relevant devices into RVAV mode. As shown in Figure 7.13.

Pressing any key while in this screen will cancel RVAV mode and return any devices previously in RVAV to normal operation.

Figure 7.13 RVAV accepted display



After 10 minutes in this screen any devices set to RVAV mode will automatically time out and return to normal operation.

7.22 Editing Device Location Text

The Edit Device Text menu allows the user to enter 20 characters of text for any loop device on the 6100.

1. Enter the user code supplied with the system and press the ↵ key to access the menus.
2. Using the ◄ and ► keys navigate to the EDIT DEVICE TEXT menu and press ↵.
3. Using the ◄ and ► keys navigate to the device address that you wish to edit the text on and press the ▲ or ▼ to enter editing mode (Figure 7.14).
4. Using the ◄ and ► keys navigate through the text characters then (the character being edited has a ^ positioned underneath it), then using the ▲ and ▼ keys, edit the character as required.
5. Press the ↵ key to accept the changes and return to the main menu.

Figure 7.14 – Edit Device Text display

7.23 Editing Zone Text

The Edit Zone Text menu allows the user to enter 20 characters of text for each of the 32 zones available on the 6100.

1. Enter the user code supplied with the system and press the ↵ key to access the menus.
2. Using the ◄ and ► keys navigate to the EDIT ZONE TEXT menu and press ↵.
3. Using the ◄ and ► keys navigate to the zone that you wish to edit the text on and press the ▲ or ▼ to enter editing mode (Figure 7.15).
4. Using the ◄ and ► keys navigate through the text characters then (the character being edited has a ^ positioned underneath it), then using the ▲ and ▼ keys, edit the character as required
5. Press the ↵ key to accept the changes and return to the main menu.

Figure 7.15 – Editing Zone Text display

7.24 Clearing the Historic Fire Event Log

The CLEAR FIRE EVENT LOG menu function allows the engineer to erase all logged fire events from the 6100 memory.

At the CLEAR FIRE EVENT LOG menu screen press the ↵ key to accept the option.

A warning screen (illustrated in figure 7.16) will be displayed to verify if events should be cleared.

Press the ↵ key to clear the fire event log and return to the main menu.

Press the ▲, ▼, ◄ or ► keys to return to the main menu without clearing the log.

Figure 7.16 Clear Fire Event Log warning display

7.25 Clearing the Historic General Event Log

The CLEAR GENERAL EVENT LOG menu function allows the user to delete all logged general events from the 6100 memory.

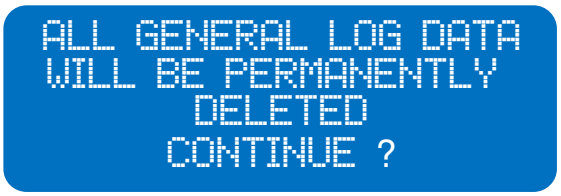
At the CLEAR GENERAL EVENT LOG menu screen press the ↵ key to accept the option.

A warning screen (illustrated in figure 7.17) will be displayed to verify if events should be cleared.

Press the ↵ key to clear the general event log and return to the main menu.

Press the ▲, ▼, ◄ or ► keys to return to the main menu without clearing the log.

Figure 7.17 Clear General Event Log warning display



7.26 Displaying Loop Device Data

The DISPLAY LOOP DEVICE DATA menu allows the engineer to view data relating to any loop device logged onto the 6100. During the commissioning phase this feature may be useful to determine the state of each loop device, the reply values for each channel and any missed replies.

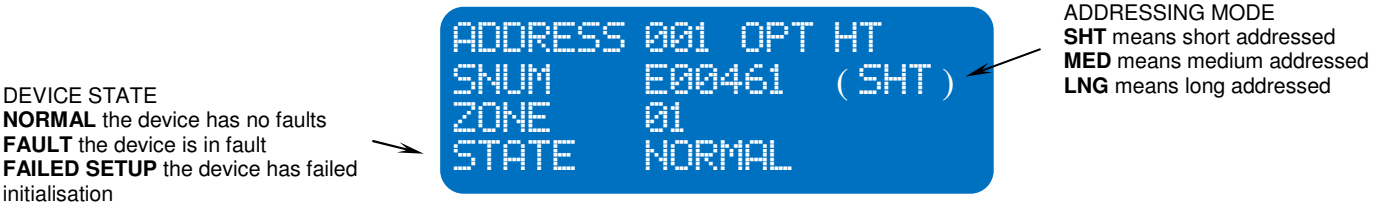
Press the ↵ key at the DISPLAY LOOP DEVICE DATA menu option. The first screen is then displayed.

Using the ◄ or ► keys locate the address of the device to be viewed.

Press the ▲ key to scroll through the data screens for the device.

Press the ↵ key at any time to return to the main menu.

Figure 7.18 Display loop device data screen 1



Screen 2 displays the current and the time averaged analogue values for the device.
Rows 2, 3 and 4 of the screen display return values for channel 1, 2 and 3 of the device. If the device does not use all channels the unused channels appear as 000.

Figure 7.19 Display loop device data screen 2

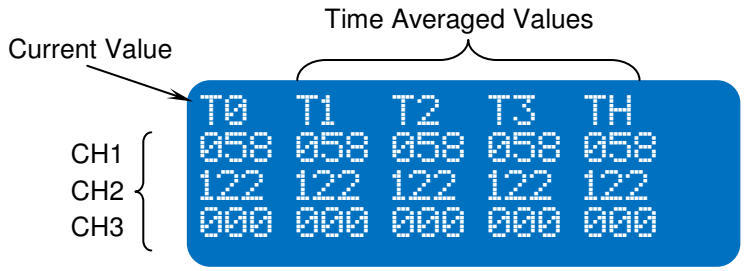


Figure 7.20 Display loop device data screen 3

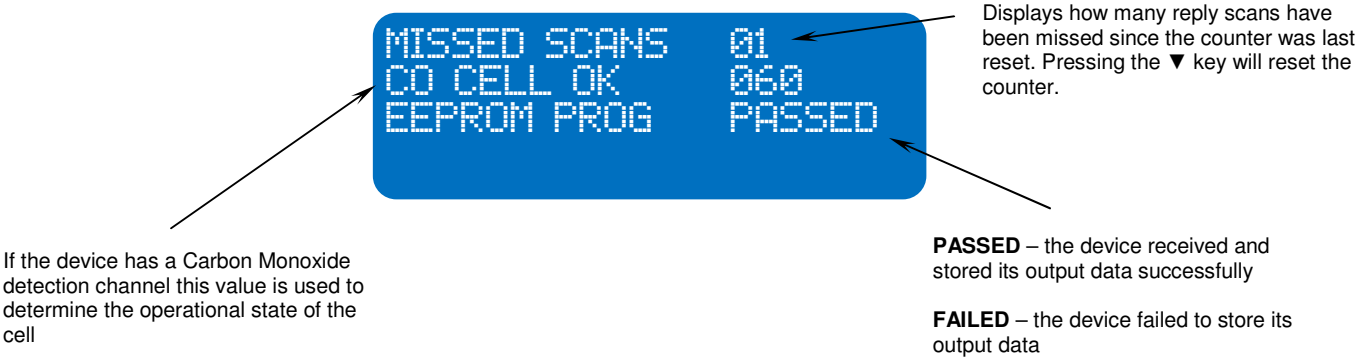
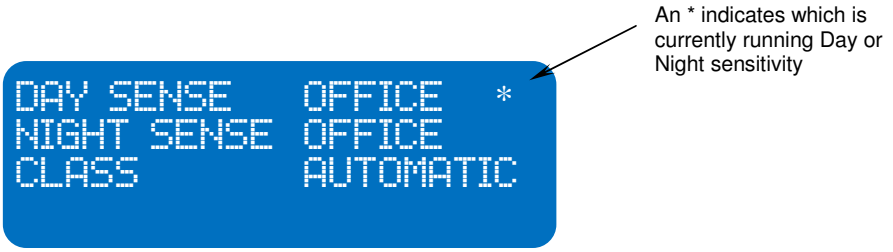


The two remaining screens show the programming data.

Figure 7.21 Display loop device data screen 4

Figure 7.22 Display loop device data screen 5



7.27 Displaying Panel Diagnostic Data

The DISPLAY DIAGNOSTIC DATA menu allows the engineer to view various values used within the panel, and can be used as an aid when diagnosing problems.

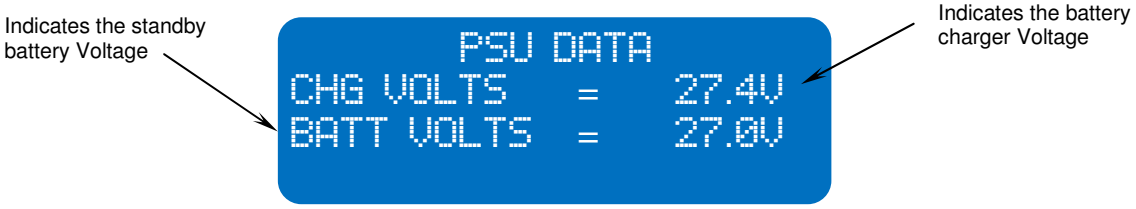
Press the ↵ key to enter the DISPLAY DIAGNOSTICS DATA menu.

Press the ▲ or ▼ keys to move through the data screens.

Press the ↵ key in any screen to return to the main menu.

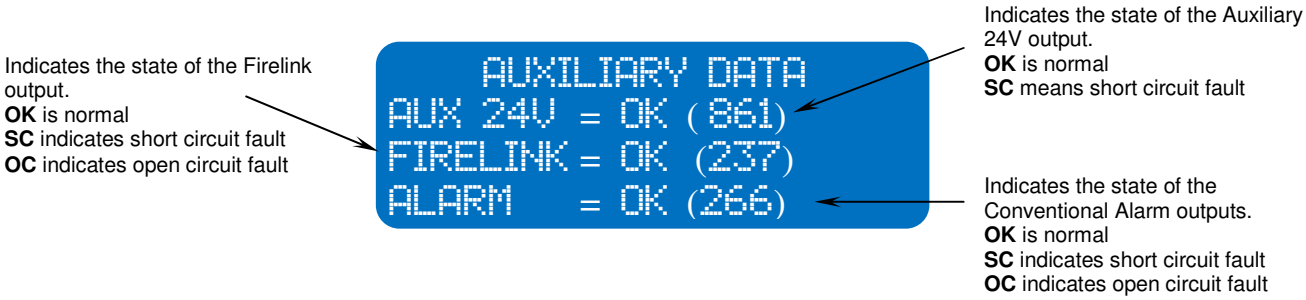
Screen 1 displays various levels associated with the 6100 power supplies.

Figure 7.23 Typically Panel Diagnostic data screen 1



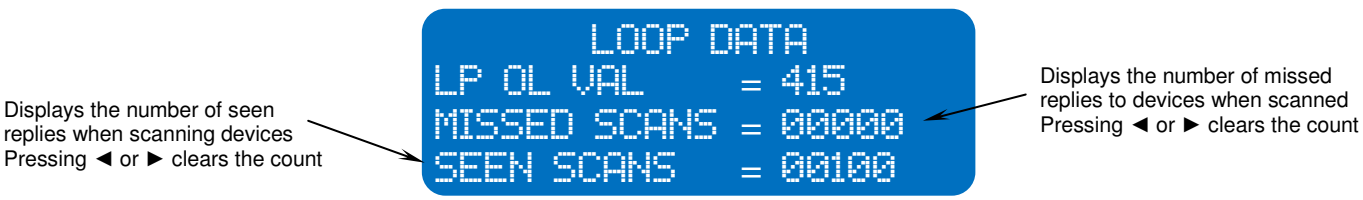
Screen 2 displays the levels read from the Auxiliary 24V, Firelink End of Line Monitoring and conventional alarm circuits. The numbers in brackets are internal data.

Figure 7.24 Panel Diagnostic data screen 1 (showing typical values)



Screen 3 displays levels associated with the loop driver circuits.
The 'missed scans' and 'seen scans' numbers may be used to determine the integrity of the loop communications by comparing how many 'good' scans versus how many 'bad' scans have been detected since the counters were reset (20 minutes of detection time is given until the counters reach the end value).

Figure 7.25 Panel Diagnostic data screen 1



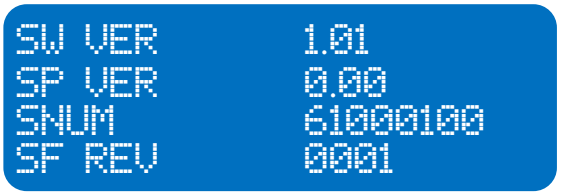
7.28 Displaying Panel Manufacturing Details

The DISPLAY PANEL DETAILS menu function allows the engineer to view the manufacturing details of the panel, which include software versions, panel serial number and the revision of the site file.

Press the ↵ key to enter the DISPLAY PANEL DETAILS menu as shown in figure 7.26.

Press the ↵ key to return to the main menu

Figure 7.26 Display Panel Data display



7.29 Connecting the 6100 to a PC

The CONNECT TO PC USING USB menu allows the engineer to connect the 6100 to a PC in order download panel firmware or update and backup the site specific settings. Consult the 6100 Programming Manual for further details.

Before entering this menu ensure that suitable software and drivers are loaded on the PC and that the USB cable is connected from the 6100 panel to the PC.

When the 6100 is connected to the PC it WILL NOT operate as a fire alarm panel and the power to the loop circuits is removed.

When the USB cable is unplugged the 6100 will automatically reset.

Connect a PC to the 6100 using the USB connection.

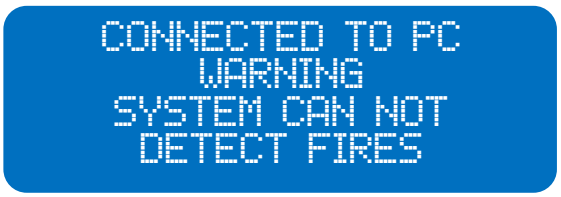
Press the ↵ key at the CONNECT TO PC USING USB menu, the 6100 will display a warning screen (illustrated in figure 7.27).

Press the ↵ key to connect to the connected PC.

Press the ▲, ▼, ◄ or ► keys to return to the main menu without connecting to the PC.

Figure 7.27 Connect to PC using USB warning display

Figure 7.28 Display shown when the 6100 is connected to the PC



7.30 Restarting the 6100

The RESTART SYSTEM menu function allows the engineer to fully reset the 6100. All loop devices will be re-programmed and re-initialised and any faults will be regenerated.

Figure 7.29 Restart System menu option

8.0 Programming the system using the Windows software suite

The 6100 Windows software suite allows all the programming aspects of the 6100 to be accessed.

Please consult the accompanying 6100 Programming Manual for details on how to commission the 6100 using a PC.

9.0 General System Operation

9.1 Panel Initialisation

When the 6100 is powered up, rebooted, or when the RESTART SYSTEM menu option is accepted the 6100 performs a full initialisation.

The initialisation consists of the following tasks and, depending on loop device types, can take up to one minute to complete.

1. Any current faults are cancelled, and any faults are re-generated.
2. All loop device running data used by the panel is reset.
3. Loop devices are reset, then reprogrammed with any relevant site specific data.
4. Automatic class loop devices are initialised as required.
5. The 6100 will log and display a Panel Reset event (which must be cleared manually).

9.2 Loop Initialisation

Automatic class loop devices require initialisation in order to calculate various running values used by the Algo-Tec™ algorithms.

Loop devices are initialised whenever the 6100 is initialised, or when a missing loop device is re-connected.

The initialisation process consists of several stabilisation scans (the exact number depends on the type of loop device) followed by four scans of each reply channel from the device.

The scan values are checked for stability, each scan value must be within 4 reply counts of any other for that channel. If a ‘ noisy ‘ device is detected the 6100 issues a ‘ Device Failed Setup ‘ event for that loop address and the device is not permitted to generate a fire. It will remain in fault until:

1. The 6100 is restarted.
2. The device is removed, seen as missing, then re-connected.
   (In this case the indicator on the loop device is illuminated for about three seconds to signal that the device is being initialised)

9.3 Added Loop Devices

The 6100 will process any devices that are stored in it’s memory. Periodically the 6100 checks for extra loop devices that may have been added. Up to 8 added devices can be detected.

Added loop devices generate a single ‘Added Loop Device ‘ event (only one event irrespective of how many devices are added). The indicator LED on the added loop device will flash at a rate of approximately 3 seconds on and 3 seconds off to signify it has been recognised by the 6100, but not fully programmed.

To enable them to operate correctly added devices must be logged on to the 6100 in the normal manner, then given a loop address and all relevant programming data as required.

10.0 6100 Technical Specification

General System Specification

Ambient Temperature Range	0 to 40 degrees Celsius
Humidity Limit	85% RH (no condensation, or icing)
Environment	Meets IP30 if mounted in a dry position that does not exceed the temperature and humidity limits given. DO NOT position in areas subject to direct sunlight.
Mounting	3 points surface mount or flush (no bezel required when flush mounting)
Standby Time (typical)	24 Hours, assuming 100mA quiescent current then 700mA in-alarm current for 30 minutes. (Note that currents are additions of panel, alarm, loop, auxiliary 24V and fire link). The exact standby time must be calculated and then verified by measurement

Power Supply Specification

Rated Voltage	100 to 240V ac rms
Rated Frequency	50 to 60 Hz
Rated Current	600mA rms
Maximum Inrush Current	20A at 240V from cold
Maximum Quiescent Load, Imax_a	647mA (22mA panel, 200mA loop, 150mA aux. 24V, 275mA battery charge)
	372mA (22mA panel, 200mA loop, 150mA aux. 24V)
Maximum Alarm Load, Imax_b	1026mA (56mA panel, 600mA loop, 200mA alarm, 150mA aux. 24V, 20mA fire-link). Batteries are not charged during an alarm condition
Minimum Load, Imin, panel only	22mA (panel normal, 30 seconds after a mains failure) 56mA (panel in alarm, 30 seconds after a mains failure)
Current Consumption from Batteries (low battery cut-off condition)	Less than 150µA (6100 is turned off)
Mains Input Fuse	1.6A time delay (not user or engineer replaceable)
Battery Type	2 x 12V 3.3Ah Sealed Lead Acid (connected in series) Only use batteries recommended by Protec (see appendix 1)
Output Voltage	24 – 29V dc with mains present , 17 – 29V dc on batteries
Output Ripple Voltage	400mV maximum (peak to peak) at full output load
Battery Charge Voltage	27.3V at 20 degrees C. Temperature compensated at – 40mV / deg C. Protected by 1.6A self resetting thermal fuse
Battery Charge Current	250mA (± 25mA)
Battery Test Load	47Ω (internal to the 6100)
Battery Over Voltage Fault Level	28.5V dc
Battery Under Voltage Fault Level	22V dc
Battery Low Voltage Cut-off Level	18.5V dc Battery Voltage (6100 turns off)
Battery Monitoring	Charger dip, battery load and internal impedance
Maximum Battery Resistance (Ri)	2Ω (battery internal resistance + lead and connection resistances)

Control Panel Specification

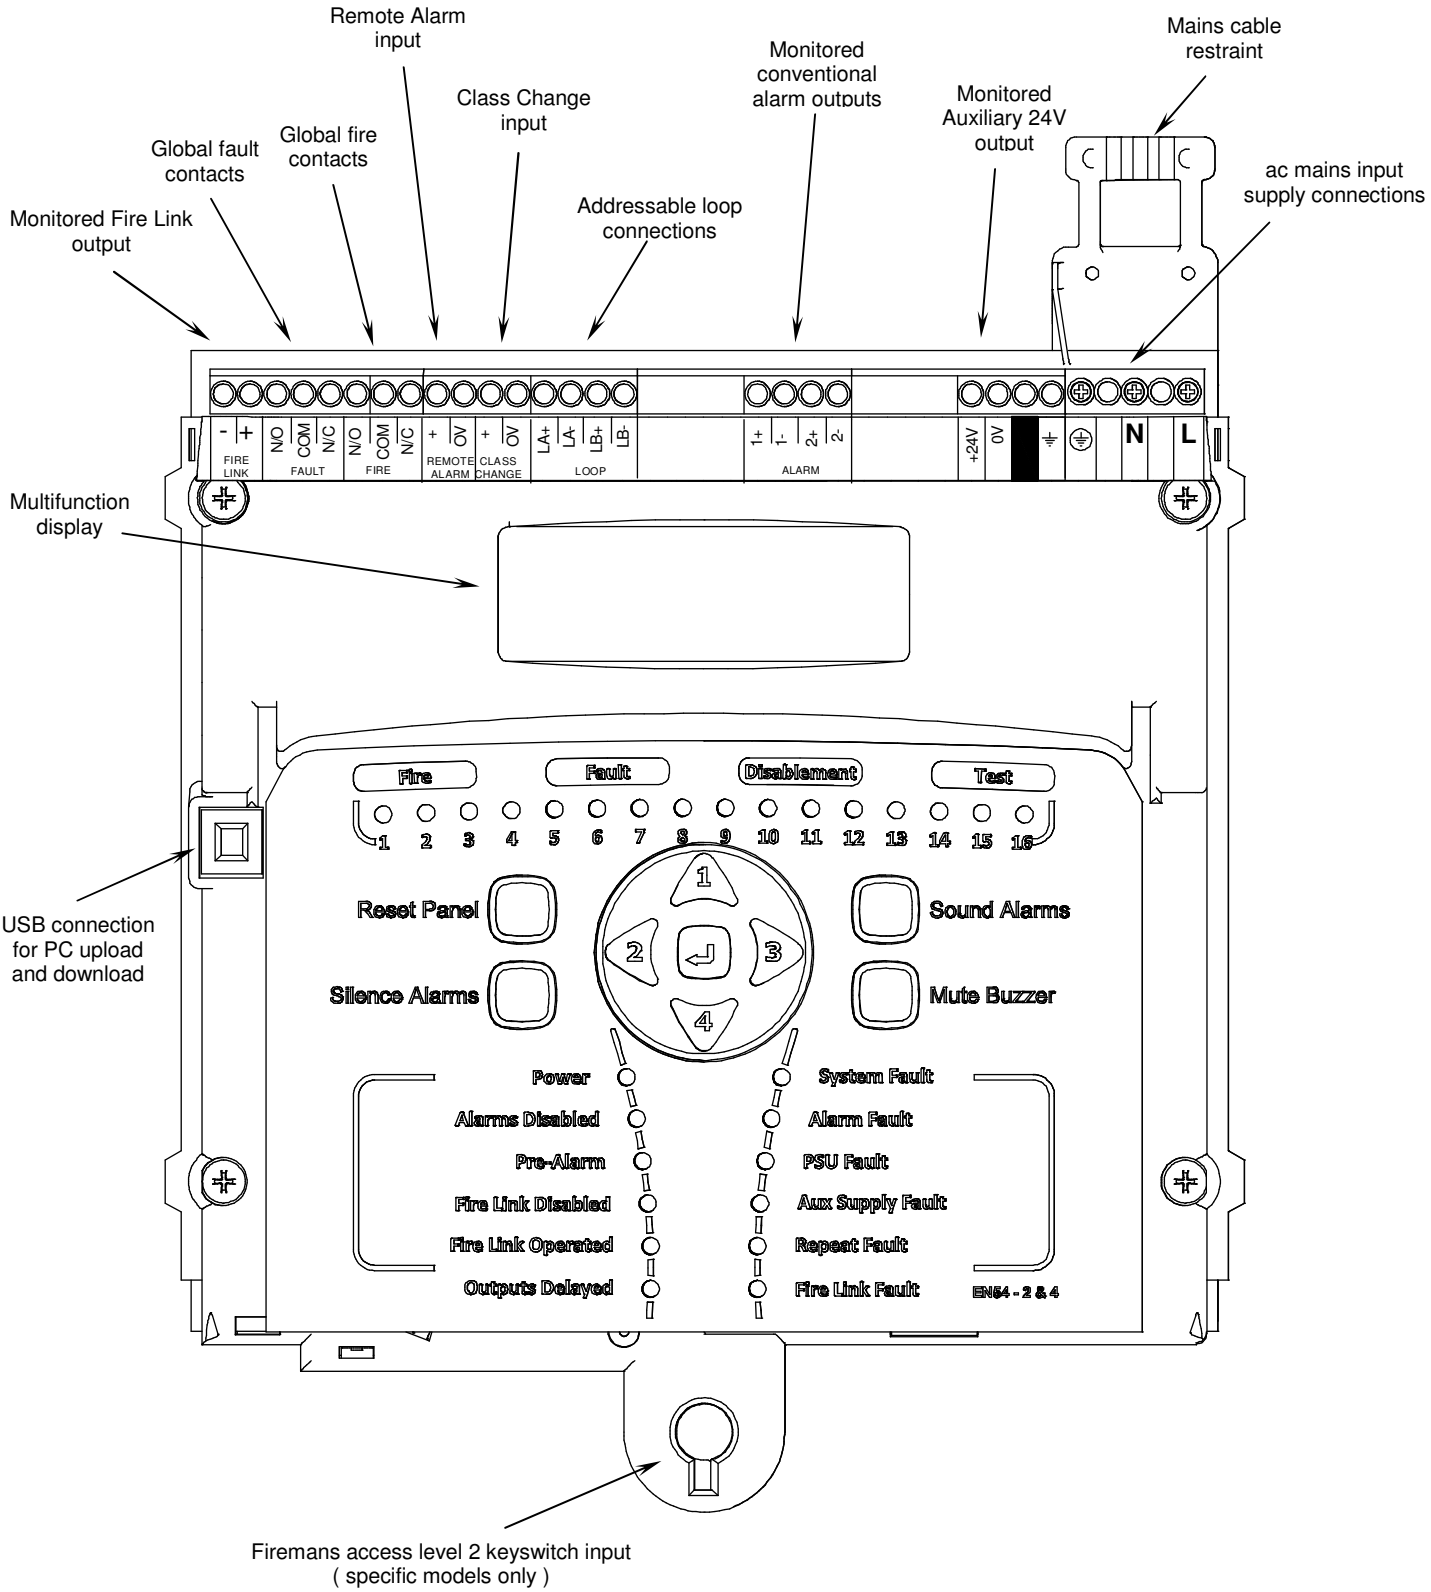
Loop Driver Output Capability	600mA average, 1.2A peak
Auxiliary 24V Output	150mA maximum (limited by monitored, self resetting thermal fuse). Any overload must be completely removed to clear a fault condition
Auxiliary 24V Fault Thresholds	An 'Aux Supply Fault' is generated when the voltage on the Aux. 24V output drops to 75% of the panel running voltage
Conventional Alarm Outputs	100mA maximum current per output, monitored for open and short circuit faults. A 10kΩ ¼W (± 5%) end of line resistor is required on each alarm output The alarm outputs can be connected in parallel to achieve a single alarm output with 200mA drive capability, in which case the end of line resistor must change to a 4.7kΩ ¼W (± 5%) ***All devices connected to the alarm outputs must be polarised and suppressed.***
Conventional Alarm Output End of Line Fault thresholds	The alarm outputs are monitored as a pair. An alarm fault is generated if the measured resistance (both alarm circuits in parallel) is above 7.5kΩ or below 2.5kΩ
Remote Alarm and Class Change Inputs	50Ω or less to activate
Fire and Fault Outputs	Volt free changeover contacts rated at a maximum of 1A 24V dc
Fire Link Output	Monitored for open and short circuit faults. Requires Protec end of line module (see appendix 1) if used to signal to a remote station, otherwise a 4.7kΩ ¼W (± 5%) termination resistor must be connected locally in the 6100
Fire link Output Current When Operated	20mA
Fire Link Output End of Line Fault thresholds	A ' Fire Link Fault ' is generated if the measured resistance is above 7.5kΩ or below 2.5kΩ

Appendix 1 List of 6100 Spares and Accessories

Description	**Protec Stock Code**
Standby battery inter connection lead	N 41-796-44
12V 3.3Ah VRLA battery (Online OL3.3-12)	N 13-120-24
6100 spares kit	N 62-587-76
6100 user manual	N 93-571-87
6100 Installation & commissioning manual (this manual)	N 93-572-88
6100 programming manual	N 93-573-89
6100 loop commissioning booklet	N 93-574-89
6100 fire link end of line module	SF 41-657-59

Appendix 2 6100 Control PCB Housing

The diagram below shows the 6100 Control PCB housing and highlights the main connections and controls.



Appendix 3 Loop Devices Supported by the 6100

Detection / Sounder Device Support

Description	Compatible from device software version
All 6000Plus devices	15

Sounder / Beacon Device Support

Description	Compatible from device software version
All 6000Plus devices	15
6000/ASB2*	28
6000/ASB4*	8
6000/ASBEA2*	4
6000/ASBEA4*	8
6000/LED/RED	1
6000/SSR2 (UK and Dutch)	31
6000/SSR/LED (UK and Dutch)	2

Input / Output Device Support

Description	Compatible from device software version
6000/MCP	11
6000/FRI	5
6000/MIP	10
6000/CCO	7
6000/MICCO	15
6000/RESET MICCO	2
6000/ZAI	9
6000/16ZAI, 6000/16ZCI, 6000/16ZOI	26
6000/16WAY I/O Interfaces (PAI and FRI)	7
6000/DIU (Damper Interface)	2
6000/LCM	1
6000/EVAC	8
6000/EVAC MIMIC	9
6000/LCD	25
6000/PROPOINT	6
6000/PROPOINTPLUS	1
6000/TSR2	1
6000/LPZA	10
6000/APZA	10
6000/2APZA	2
6000/2LPZA	2
6000/2IO	2
6000/4IO	2
6000/VAD/C/x (x = RED or WHITE)	20
6000/VAD/W/x (x = RED or WHITE)	20
6000/TSx/VAD (x = R or W depending on colour)	20

* Any non 6000*PLUS* series detection device attached to this device is **not** supported by the 6100.

Appendix 4 6100 Event Descriptions

DEVICE IN ALARM
The loop device at the address shown has entered the alarm state.

DEVICE FAULT
The loop device at the address shown has entered the fault state. It may no longer be operating correctly and must be investigated immediately.

DEVICE FAILED SETUP
The loop device at the address shown has failed to setup correctly when the system initialised. The device will not detect fires. The system must be restarted, or the device must be removed for 30 seconds, then replaced to attempt to rectify the fault.

DEVICE PREALARM
The loop device at the address shown has detected a level of smoke, heat or carbon monoxide that is indicative of a fire but not quite at the fire threshold. To view devices in pre-alarm, use the 'View Faults' menu.

DEVICE DISABLED
The device at the address shown has been disabled. Activations from this device **will not** generate an alarm. If the device develops a fault, the fault **will not** be registered on the 6100. Disabled output devices will still activate.

ZONE IN TEST
The zone shown has been programmed into walk test mode.

ZONE DISABLEMENT
The zone shown has been disabled. Activations from devices in this zone **will not** generate an alarm. If devices in this zone develop a fault, the fault **will not** be registered on the 6100. Disabled output devices will still activate.

ZONE FAULT
One, or more, loop devices in this zone have developed a fault.

ALARM FAULT
A fault has been detected with an alarm output device on the loop, or a fault has been detected on one or both of the conventional alarm outputs.

ALARMS DISABLED
The alarm outputs have been disabled. Alarm outputs from loop devices, or connected to the conventional alarm outputs will not activate.

FIRE LINK FAULT
A fault has been detected on the fire link output. The fire link may not operate when the 6100 detects a fire.

FIRE LINK DISABLED
The fire link output has been disabled. Fire link faults and activations will not occur.

BATTERY FAULT
The 6100 has detected a fault with the internal standby battery. This may be due to a fault with the batteries, or the connections to the batteries. The 6100 may not operate correctly in the event of a mains failure.

REPEAT FAULT
A fault has been detected with one, or more loop powered LCD repeat units.

AUX SUPPLY FAULT
A fault has been detected with the Auxiliary 24V output. This may be a wiring fault, or the output may have been overloaded. The connection to the auxiliary 24V output must be disconnected for 10 seconds to allow the internal thermal ‘fuse’ to reset.

CLASS CHANGE
The Class Change input (if enabled) has been operated.

REMOTE ALARM
The Remote Alarm input (if enabled) has been operated.

USER CODE ENTERED
ENG CODE ENTERED
ADV ENG CODE ENTERED
The relevant code entry sequence has been entered into the 6100.

PANEL RESET
The 6100 has been reset either via the menu system, or the 6100 has been powered up from cold.

LOOP FAULT
A fault, or overload has been detected on the loop driver outputs. This may be due to an open circuit loop wiring fault, a short circuit loop wiring fault or a fault on a loop device. This event can take up to 5 minutes to clear once the fault condition has been rectified.

PC CONNECTED
The 6100 has been connected to a PC to upgrade its operating system or site specific data.

SITE DATA CORRUPT
An error has been detected in the site specific data memory.

ADDED DEVICE FAULT
One, or more new loop devices have been detected on the 6100 loop. Added devices must be logged onto the system in order for them to function correctly.

LOOP ALARM FAULT
A fault has been detected with one, or more loop alarm output devices. One or more loop alarm output devices may no longer operate correctly.

LOOP LOGGED
The loop devices on the 6100 have been logged.

SITE DATA CHANGED
The site specific data memory has been altered. This may be due to logging, allocating and saving new loop devices or editing device or zone text.

NIGHT SENS ON
The 6100 has switched from day sensitivity operation to night sensitivity operation.

EVAC PNL ACTIVE
A 6000 series loop evacuation panel has activated the 6100.

OP GROUP DISABLED
The output group shown has been disabled. Devices programmed into this output group will no longer activate.

SITEFILE ERROR
The revision of ‘site file’ in the 6100 is incompatible with the version of 6100 operating system.

The correct ‘site file’ revision must be programmed into the 6100, or the operating system must be updated as required.

Designed and manufactured in the United Kingdom
